(57) **ABSTRACT**

A resistive memory device capable of implementing a multi-level cell, a method of fabricating the same, and a memory apparatus and data processing system including the same are provided. The resistive memory device includes a lower electrode, a first phase-change material layer formed over the lower electrode, a second phase-change material layer formed to surround an outer sidewall of the first phase-change material layer, and an upper electrode formed over the first phase-change material layer and the second phase-change material layer.

CROSS-REFERENCES TO RELATED APPLICATION

This application is a division of U.S. patent application Ser. No. 13/719,733 filed on Dec. 19, 2012, which claims priority under 35 U.S.C. 119(a) to Korean application number 10-2012-0093198, filed on Aug. 24, 2012, in the Korean Patent Office. The disclosure of each of the foregoing application is incorporated by reference in its entirety.

BACKGROUND OF THE INVENTION

1. Technical Field

The embodiments of the present invention relate to a semiconductor integrated device, and more particularly, to a resistive memory device, a method of fabricating the same, and a memory apparatus and a data processing system having the same.

2. Related Art

Dynamic Random Access Memories (DRAMs) operate at high speed, but the DRAMs are volatile. Flash memories are highly integrated and nonvolatile, but the flash memories may not guarantee operation speed equivalent to DRAM operation speed.

Studies on memory devices having advantages of the DRAMs and flash memories have been actively progressed, and resistive memory devices that are nonvolatile and operate at a high speed have been suggested.

The resistive memory devices are a memory device using a variable resistive material, which switches at least two resistance states by rapid resistance change based on an applied voltage. There are phase-change RAMs (PCRAMs) and resistive RAMs (ReRAMs) memory devices as the resistive memory devices.

The PCRAMs store data by changing a crystalline state of the variable resistive material with current applied to a heating electrode. The PCRAMs have advantages of a nonvolatile property, high operation speed, stability, unnecessary of an erase operation, endurance, and support for access in units of bytes.

The PCRAMs have to be designed to support a multi-level cell (MLC) structure to obtain large capacity and high integration. The PCRAMs having the MLC structure, which have been studied until recently, are implanted using a method of controlling a pulse applied to memory cells having the same structure as a single-level cell (SLC).

That is, the current PCRAMs have to accurately control a pulse type applied to implement the MLC, and this is because a set/reset state of data becomes transited depending on crystallization of a phase-change material. When the property of the phase-change material is changed by repetitive use of the PCRAMs, undesired data is written, and thus, there are limitations to implement MLC through the same structure as SLC.

SUMMARY

In accordance with an embodiment of the present invention, the resistive memory device may include a lower electrode, a first phase-change material layer formed over the lower electrode, a second phase-change material layer formed to surround an outer sidewall of the first phase-change

2

material layer, and an upper electrode formed over the first phase-change material layer and the second phase-change material layer.

In accordance with another embodiment of the present invention, the method of manufacturing a PCRAM device may include providing a semiconductor substrate in which a lower electrode is formed, sequentially forming a first phase-change material layer, an electrode layer, and a hard mask over the semiconductor substrate in which the lower electrode is formed, patterning the hard mask, the electrode layer, and the first phase-change material layer so that the first phase-change material layer is in contact with the lower electrode, and doping and curing a preset combination element into the first phase-change material layer to change an outer circumference of the first phase-change material layer to a second phase-change material layer having a predetermined thickness.

In accordance with another embodiment of the present invention, the resistive memory apparatus may include a memory cell array including a plurality of memory cells connected between word lines and bit lines, and a controller configured to control data write and data read for a selected memory cell in the memory cell array. Each of the plurality of memory cells may include a resistive device and a selection device. The resistive device may include a lower electrode, a first phase-change material layer formed over the lower electrode, a second phase-change material layer formed to surround an outer sidewall of the first phase-change material layer, and an upper electrode formed over the first phase-change material layer and the second phase-change material layer.

In accordance with another embodiment of the present invention, the data processing system may include a resistive memory apparatus, which includes a memory cell array including a plurality of memory cells connected to bit lines and word lines, each of memory cells including a resistive device and a selection device, and a controller configured to control an operation of the memory cell array, and a memory controller configured to access the resistive memory apparatus in response to request of a host. The resistive device may include a lower electrode, a first phase-change material layer formed over the lower electrode, a second phase-change material layer formed to surround an outer sidewall of the first phase-change material layer, and an upper electrode formed over the first phase-change material layer and the second phase-change material layer.

In accordance with another embodiment of the present invention, the data processing system may include a processor, an operation memory configured to store an application, data, and a control signal required for an operation of the processor, a resistive memory apparatus that includes a memory cell array including a plurality of memory cells connected to bit lines and word lines, each of memory cells including a resistive device and a selection device, and a user interface configured to perform data input/output (I/O) between the processor and a user. The resistive device may include a lower electrode, a first phase-change material layer formed on the lower electrode, a second phase-change material layer formed to surround an outer sidewall of the first phase-change material layer, and an upper electrode formed over the first phase-change material layer and the second phase-change material layer.

These and other features, aspects, and embodiments are described below in the section entitled "DETAILED DESCRIPTION".

BRIEF DESCRIPTION OF THE DRAWINGS

The above and other aspects, features and other advantages of the subject matter of the present disclosure will be more

clearly understood from the following detailed description taken in conjunction with the accompanying drawings, in which:

FIGS. 1 to 4B are views illustrating a method of fabricating a resistive memory device according to an exemplary embodiment of the inventive concept;

FIGS. 5 and 6 are line graphs illustrating operation characteristic of a variable resistive material applied to the inventive concept;

FIG. 7 is a block diagram illustrating a configuration of a memory apparatus according to an exemplary embodiment of the inventive concept;

FIG. 8 is a block diagram illustrating a configuration of a data processing system according to an exemplary embodiment of the inventive concept; and

FIG. 9 is a block diagram illustrating a configuration of a data processing system according to another exemplary embodiment of the inventive concept.

DETAILED DESCRIPTION

Hereinafter, exemplary embodiments will be described in greater detail with reference to the accompanying drawings.

Exemplary embodiments are described herein with reference to cross-sectional illustrations that are schematic illustrations of exemplary embodiments (and intermediate structures). As such, variations from the shapes of the illustrations as a result, for example, of manufacturing techniques and/or tolerances, are to be expected. Thus, exemplary embodiments should not be construed as limited to the particular shapes of regions illustrated herein but may be to include deviations in shapes that result, for example, from manufacturing. In the drawings, lengths and sizes of layers and regions may be exaggerated for clarity. Like reference numerals in the drawings denote like elements. It should be readily understood that the meaning of “on” and “over” in the present disclosure should be interpreted in the broadest manner such that “on” not only means “directly on” something but also include the meaning of “on” something with an intermediate feature or a layer therebetween, and that “over” not only means the meaning of “over” something may also include the meaning it is “over” something with no intermediate feature or layer therebetween (i.e., directly on something).

FIGS. 1 to 4B are views illustrating a method of fabricating a resistive memory device according to an exemplary embodiment of the inventive concept.

First, a first phase-change material layer 103, electrode layers 105 and 107, and a hard mask 109 are sequentially formed on a semiconductor substrate 101 in which a bottom structure is formed.

An access device and a lower electrode may be formed in the semiconductor substrate 101, and a word line may be further formed on the semiconductor substrate 101. The bottom structure may be designed using various types and methods and is beyond the scope of the inventive concept, and thus, detailed description thereof will be omitted.

The electrode layers 105 and 107 may have a stacked structure of a titanium layer 105 and a titanium nitride layer 107, but the electrode layers are not limited to the stacked structure.

The first phase-change material layer 103 may be selected from a material in which a crystalline state is changed based on the applied current. For example, the first phase-change material layer 103 may be formed using a binary chalcogenide compound, for example, germanium (Ge)-tellurium (Te).

Referring to FIG. 2A, the hard mask 109 is patterned using a photoresist film (not shown) and then, the electrode layers 107 and 105 and the first phase-change material layer 103 are patterned using the patterned hard mask as an etch mask. At this time, the patterned structure may be formed to have a cylindrical shape of cross-section, but the patterned structure is not limited thereto.

Through the patterning process, a top of the first phase-change material layer 103 is shielded by the electrode layers 105 and 107 and the hard mask 109, a bottom thereof is shielded by the semiconductor substrate 101, and thus only sides thereof are exposed.

FIG. 2B illustrates a layout diagram after the process of FIG. 2A is completed.

Referring to FIG. 3, a preset combination element 111 is doped into the semiconductor substrate 101 in which the patterned structure is formed. The combination element 111 may be selected from a material, which is chemically combined with a component of the first phase-change material layer 103, to represent resistance change characteristic. If the first phase-change material layer 103 includes, for example, Ge—Te, the material that is chemically combined with Ge—Te to represent the resistance change characteristic may be antimony (Sb).

In FIG. 3, the combination element 111 to be combined with the first phase-change material layer 130 may be doped using a plasma doping (PLAD) method and controlled to be isotropically doped. At this time, materials (the hard mask 109 and the electrode layers 105 and 107) other than the exposed surface of the first phase-change material layer 103 are amorphous, and thus, the combination element 111 is not well doped into the amorphous material. Therefore, the selective doping only into the sidewall of the first phase-change material layer 103 is possible.

The doping energy is controlled so that the combination element 111 is doped only into the sidewall of the first phase-change material layer 103 and therefore, a phase-change material pattern is to be formed in a core-shell structure in a subsequent process.

A cleaning process for removing the combination element 111 doped in an undesired portion is performed and then a low temperature curing process for stabilizing the combination element 111 is performed. Therefore, as shown in FIG. 4A, a second phase-change material layer 113 is formed to surround the sidewall of the first phase-change material layer 103.

FIG. 4B illustrates a plan view of the resistive memory device illustrated in FIG. 4A, wherein FIG. 4B illustrates a plan view illustrating a portion in which the first and second phase-change material layers 103 and 113 are formed.

As shown in FIG. 4B, the first phase-change material layer 103 is formed in a center position, that is, in a core. The first phase-change material layer 103 is in contact with the lower electrode (not shown), and thus is changed in the crystallization state by the heat applied through the lower electrode. The second phase-change material layer 113 may be formed in a shell surrounding an outer circumference of the center position.

On the other hand, a thickness of the second phase-change material layer 113 may be determined based on a process parameter in the curing process and composition of the second phase-change material layer 113 may be also determined. The thickness and composition of the first and second phase-change material layers 103 and 113 may be parameters for implementing the MLC, and therefore, the MLC may be

5

fabricated through only simple change of the process parameter for determining a curing condition in the inventive concept.

In the resistive memory device as formed, the first phase-change material layer **103** formed in the core and the second phase-change material layer **113** formed in the shell have electric properties from each other.

If the first phase-change material layer **103** is formed of Ge—Te, the second phase-change material layer **113** may include germanium (Ge)-antimony (Sb)-tellurium (Te) (GST) using Sb as the combination element **111**. Ge—Te has a high melting point and low crystallization speed compared to GST. Therefore, the MLC may be implemented using the electric property difference.

FIGS. **5** and **6** are views illustrating operation characteristic of a variable resistive material applied to the inventive concept.

First, FIG. **5** illustrates voltage-current characteristic of the GST material and the Ge—Te material. It can be seen from FIG. **5** that the GST material **A1** has lower resistance compared to the Ge—Te material **B1**.

FIG. **6** is a graph illustrating resistance change when a write current is applied to the GST material **A2** and the Ge—Te material **B2**. It can be seen from FIG. **6** that the resistance change in the Ge—Te material **B2** easily occurs even in the low write current while the GST material **A2** needs higher write current than the Ge—Te material **B2**.

Actually, the Ge—Te material has a melting point of 725° C. in a bulk state and the GST material has a low melting point of 616° C. As shown in FIGS. **5** and **6**, the crystallization state in the Ge—Te material is changed in lower current than the GST material according to the melting property. Therefore, the melting property is applied to the ReRAM to enable the MLC to be implemented.

The phase-change material layer may include a GST single layer in the general phase-change memory device. Therefore, only two states of the crystallization state and the amorphous state in the GST material are used as a data storage property. Thus, precise current control is necessary to implement MLC in the general PCRAM including the GST single layer.

However, in the PCRAM of the exemplary embodiment, the phase-change material layer is formed in the core-shell structure and in particular, the phase-change material layer in the core includes a material having a melting point higher than the phase-change material layer in the shell. A heating electrode may be in contact only with the phase-change material layer in the core, and thus, resistance state of the phase-change material layer in the shell is changed by the heat conducted from the phase-change material layer in the core.

That is, the phase-change material layer is formed by the core-shell dual structure having different electric properties from each other to easily control the resistance state, and thus, MLC may be implemented.

FIG. **7** is a view illustrating a configuration of a memory apparatus according to an exemplary embodiment of the inventive concept.

Referring to FIG. **7**, a memory apparatus **300** according to the exemplary embodiment of the inventive concept includes a memory cell array **310**, a decoder **320**, a read/write circuit **330**, an input/output (I/O) buffer **340**, and a controller **350**.

Each of a plurality of memory cells included in the memory cell array **310** may be configured to include the resistive memory device illustrated in FIG. **4A**. Furthermore, the plurality of memory cells in the memory cell array **310** are connected to the decoder **320** through a word line WL. The

6

plurality of memory cells in the memory cell array **310** are also connected to the read/write circuit **330** through a bit line BL.

The decoder **320** receives an external address ADD and decodes a row address and a column address to be accessed in the memory cell array **310** by control of the controller **350**, which operates according to a control signal CTRL.

The read/write circuit **330** receives data DATA from the I/O buffer **340** and writes data in a selected memory cell of the memory cell array **310** under the control of the controller **350** or provides data read from a selected memory cell of the memory cell array **310** to the I/O buffer **340** under the control of the controller **350**.

FIG. **8** is a block diagram illustrating a configuration of a data processing system according to an exemplary embodiment of the inventive concept.

A data processing system **400** illustrated in FIG. **8** may include a memory controller **420** connected between a host and a resistive memory apparatus **410**.

The memory controller **420** may be configured to access the resistive memory apparatus **410** in response to request of the host, and thus, the memory controller **420** may include a processor **4201**, an operation memory **4203**, the host interface **4205**, and a memory interface **4207**.

The processor **4201** may control an overall operation of the memory controller **420**, and the operation memory **4203** may store an application, data, a control signal, and the like, required for operation of the memory controller **420**.

The host interface **4205** performs protocol conversion for exchange of data/control signal between the host and the memory controller **420**. The memory interface **4207** performs protocol conversion for exchange of data/control signal between the memory controller **420** and the resistive memory apparatus **410**.

The resistive memory apparatus **410** may include a memory cell array configured of unit memory cells each including a resistive device, in which the variable resistive material is formed between two electrode layers, and a selection device. In particular, the resistive device may be a resistive device using a first phase-change material layer formed in a center position thereof and a second phase-change material layer formed to surround an outer circumference of the first phase-change material layer as a variable resistive material layer.

In the exemplary embodiment of the inventive concept, the data processing system illustrated in FIG. **8** may be a memory card, but the data processing system is not limited thereto.

FIG. **9** is a view illustrating a configuration of a data processing system according to another exemplary embodiment of the inventive concept.

A data processing system **500** illustrated in FIG. **9** includes a resistive memory apparatus **510**, a processor **520**, an operation memory **530**, and a user interface **540**. If necessary, the data processing system **500** may further include a communication module **550**.

The processor **520** may be a central processing unit (CPU), and the operation memory **530** may store an application program, data, a control signal, and the like, required for an operation of the data processing system **500**. The user interface **540** provides an environment accessible to the data processing system **500** by the user and provides a data processing procedure, result, and the like of the data processing system **500** to the user.

For example, the resistive memory apparatus **510** may include a memory cell array configured of unit memory cells each including a resistive memory device illustrated in FIG. **4A** and a selection device. In particular, the phase-change

7

material layer included in the resistive device may include a first phase-change material layer formed in a central portion thereof and a second phase-change material layer formed to surround an outer circumference of the first phase-change material layer.

On the other hand, the data processing systems illustrated in FIGS. 8 and 9 may be used as a disc apparatus, a built in/external memory card of a mobile electronic apparatus, an image processor, and other application chipsets.

The above embodiments of the present invention are illustrative and not limitative. Various alternatives and equivalents are possible. The invention is not limited by the embodiment described herein. Nor is the invention limited to any specific type of semiconductor device. Other additions, subtractions, or modifications are obvious in view of the present disclosure and are intended to fall within the scope of the appended claims.

What is claimed is:

1. A method of fabricating a resistive memory device, the method comprising:

providing a semiconductor substrate in which a lower electrode is formed;

sequentially forming a first phase-change material layer, an electrode layer, and a hard mask over the semiconductor substrate in which the lower electrode is formed;

8

patterning the hard mask, the electrode layer, and the first phase-change material layer so that the first phase-change material layer is in contact with the lower electrode; and

doping and curing a preset combination element into the first phase-change material layer to change an outer circumference of the first phase-change material layer to a second phase-change material layer having a predetermined thickness.

2. The method of claim 1, wherein the first phase-change material layer is formed using a binary chalcogenide compound.

3. The method of claim 2, wherein the binary chalcogenide compound is a germanium-tellurium (Ge—Te) compound.

4. The method of claim 3, wherein the combination element is antimony (Sb).

5. The method of claim 1, wherein the combination element is doped by a plasma doping method.

6. The method of claim 1, wherein a thickness and composition of the second phase-change material layer are determined based on a curing process parameter.
